## Package: tram (via r-universe)

October 17, 2024

Title Transformation Models

**Version** 1.1-2 **Date** 2024-10-02

Description Formula-based user-interfaces to specific transformation models implemented in package 'mlt'. Available models include Cox models, some parametric survival models (Weibull, etc.), models for ordered categorical variables, normal and non-normal (Box-Cox type) linear models, and continuous outcome logistic regression (Lohse et al., 2017,

<DOI:10.12688/f1000research.12934.1>). The underlying theory is described in Hothorn et al. (2018) <DOI:10.1111/sjos.12291>. An extension to transformation models for clustered data is provided (Barbanti and Hothorn, 2022,

<DOI:10.1093/biostatistics/kxac048>). Multivariate conditional transformation models (Klein et al, 2022,

<DOI:10.1111/sjos.12501>) and shift-scale transformation models (Siegfried et al, 2023, <DOI:10.1080/00031305.2023.2203177>) can be fitted as well.

**Depends** R (>= 3.5.0), mlt (>= 1.6-0), mvtnorm (>= 1.3-0)

**Imports** Formula, multcomp, variables (>= 1.0-4), basefun (>= 1.1-2), sandwich, stats, survival, graphics, Matrix, methods

Suggests MASS, TH.data, trtf (>= 0.3-3), mlbench, knitr, quantreg, colorspace, ATR, lme4, merDeriv, SparseGrid, alabama, numDeriv, gridExtra, lattice, latticeExtra, HSAUR3, ordinalCont, coxme, mlt.docreg, ordinal, coin, asht, gamlss, randomForestSRC

## Description

Aalen model with fully parameterised hazard function

## Usage

```
Aareg(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

## Arguments

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.

Aareg 3

```
na.action a function which indicates what should happen when the data contain NAs. The default is set to na.omit.additional arguments to tram.
```

#### **Details**

This function allows simultaneous estimation of the cumulative hazard parameterised by a Bernstein polynomial. The model is typically fitted with time-varying coefficients, all types of random censoring and trunction are allowed.

The responses is bounded (bounds = c(0, Inf)) when specified as a Surv object. Otherwise, bounds can be specified via ....

#### Value

An object of class Aareg, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

#### References

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

```
data("GBSG2", package = "TH.data")
library("survival")
GBSG2$time <- as.numeric(GBSG2$time)</pre>
GBSG2$y <- with(GBSG2, Surv(time, cens))</pre>
### Cox proportional hazards model
m1 <- Coxph(y \sim horTh, data = GBSG2, support = c(1, 1500))
logLik(m1)
### Aalen additive hazards model with time-varying effects
m2 \leftarrow Aareg(y \mid horTh \sim 1, data = GBSG2, support = c(1, 1500))
logLik(m2)
### compare the hazard functions
nd <- data.frame(horTh = unique(GBSG2$horTh))</pre>
col <- 1:2
lty <- 1:2
plot(as.mlt(m1), newdata = nd, type = "hazard",
     col = col, lty = lty[1], xlab = "time")
plot(as.mlt(m2), newdata = nd, type = "hazard",
     col = col, lty = 2, add = TRUE)
legend("topright", col = rep(col, each = 2),
       lty = rep(1:2), bty = "n",
       legend = paste(rep(paste("horTh:",
                                  levels(nd$horTh)), each = 2),
                       rep(c("Cox", "Aalen"), 2)))
```

4 BoxCox

BoxCox	(Similar to) Box-Cox Models
ZONOON	(ommen to) bon con mount

## Description

Non-normal linear regression inspired by Box-Cox models

#### Usage

```
BoxCox(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to na.omit.
• • •	additional arguments to tram.

#### **Details**

A normal model for transformed responses, where the transformation is estimated from the data simultaneously with the regression coefficients. This is similar to a Box-Cox transformation, but the technical details differ. Examples can be found in the package vignette.

The model is defined with a negative shift term. Large values of the linear predictor correspond to large values of the conditional expectation response (but this relationship is potentially nonlinear).

## Value

An object of class BoxCox, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

Colr 5

#### References

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

## **Examples**

Colr

Continuous Outcome Logistic Regression

## Description

A proportional-odds model for continuous variables

#### Usage

```
Colr(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

## Arguments

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset.
	additional arguments to tram.

6 Compris

#### **Details**

Simultaneous estimation of all possible binary logistic models obtained by dichotomisation of a continuous response. The regression coefficients can be constant allowing for an interpretation as log-odds ratios.

The model is defined with a positive shift term, thus exp(coef()) is the multiplicative change of the odds ratio (conditional odds of treatment or for a one unit increase in a numeric variable divided by conditional odds of reference). Large values of the linear predictor correspond to small values of the conditional expectation response (but this relationship is nonlinear).

#### Value

An object of class Colr, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

#### References

Tina Lohse, Sabine Rohrmann, David Faeh and Torsten Hothorn (2017), Continuous Outcome Logistic Regression for Analyzing Body Mass Index Distributions, *F1000Research*, **6**(1933), doi:10.12688/f1000research.12934.1.

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

#### **Examples**

Compris

Competing Risk Regression

#### Description

An alternative approach to competing risk regression via multivariate transformation models

## Usage

Compris 7

```
NPlogLik = FALSE, theta = NULL,
optim = mltoptim(auglag = list(maxtry = 5)),
args = list(seed = 1, type = c("MC", "ghalton"), M = 1000),
scale = FALSE, ...)
```

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under Details and in the package vignette. The left-hand side must be a Surv object, where "event" is specified by a factor that has levels indicating the independent censoring event, the primary event of interest and then the competing events (in this order).
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of case weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to na.omit.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
primary	a character defining the marginal model for the primary event of interest, that is, the first status level.
competing	a character defining the marginal models for the remaining competing events.
NPlogLik	logical, optimise nonparametric likelihood defined in terms of multivariate probabilities.
theta	optional starting values.
optim	see Mmlt.
args	a list of arguments for lpmvnorm.
scale	logical defining if variables in the linear predictor shall be scaled. Scaling is internally used for model estimation, rescaled coefficients are reported in model output.
	addition arguments passed to primary or competing model function.

#### **Details**

This is a highly experimental approach to an alternative competing risk regression framework described by Czado and Van Keilegom (2023) and Deresa and Van Keilegom (2023).

#### Value

An object of class Mmlt, allowing to derive marginal time-to-event distributions for the primary event of interest and all competing events.

8 Compris

Coxph

Cox Proportional Hazards Model

#### **Description**

Cox model with fully parameterised baseline hazard function

#### **Usage**

```
Coxph(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

10 Coxph

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to na.omit.
	additional arguments to tram.

#### **Details**

The original implementation of Cox models via the partial likelihood, treating the baseline hazard function as a nuisance parameter, is available in coxph. This function allows simultaneous estimation of the log-hazard ratios and the log-cumulative baseline hazard, the latter parameterised by a Bernstein polynomial. The model can be fitted under stratification (time-varying coefficients), all types of random censoring and trunction. An early reference to this parameterisation is McLain and Ghosh (2013).

The response is bounded (bounds = c(0, Inf)) when specified as a Surv object. Otherwise, bounds can be specified via . . . .

Parameters are log-hazard ratios comparing treatment (or a one unit increase in a numeric variable) with a reference.

## Value

An object of class Coxph, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

## Not run: confint(perm_test(m2))
```

Lehmann

Proportional Reverse Time Hazards Linear Regression

## Description

Non-normal linear regression for Lehmann-alternatives

#### Usage

```
Lehmann(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.

12 Lm

offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to na.omit.
	additional arguments to tram.

#### **Details**

This transformation model uses the cumulative distribution function for the standard Gumbel maximum extreme value distribution to map the shifted transformation function into probabilities. The exponential of the shift paramater can be interpreted as a Lehmann-alternative or reverse time hazard ratio.

#### Value

An object of class Lehmann, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

#### References

Erich L. Lehmann (1953), The Power of Rank Tests, *The Annals of Mathematical Statistics*, **24**(1), 23-43.

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

#### **Examples**

Lm

Normal Linear Model

#### **Description**

Normal linear model with benefits

#### Usage

```
Lm(formula, data, subset, weights, offset, cluster, na.action = na.omit, ...)
```

Lm 13

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to na.omit.
	additional arguments to tram.

#### **Details**

A normal linear model with simulaneous estimation of regression coefficients and scale parameter(s). This function also allows for stratum-specific intercepts and variances as well as censoring and truncation in the response.

Note that the scale of the parameters is different from what is reported by 1m; the discrepancies are explained in the package vignette.

The model is defined with a negative shift term. Large values of the linear predictor correspond to large values of the conditional expectation response.

#### Value

An object of class Lm, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

#### References

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

14 Mmlt

Mmlt

Multivariate Conditional Transformation Models

#### **Description**

Conditional transformation models for multivariate continuous, discrete, or a mix of continuous and discrete outcomes

#### Usage

#### **Arguments**

... marginal transformation models, one for each response, for Mmlt. Additional

arguments for the methods.

formula a model formula describing a model for the dependency structure via the lambda

parameters. The default is set to ~ 1 for constant lambdas.

data a data.frame.

conditional logical; parameters are defined conditionally (only possible when all models are

probit models). This is the default as described by Klein et al. (2022). If FALSE, parameters can be directly interpreted marginally, this is explained in Section 2.6 by Klein et al. (2022). Using conditional = FALSE with probit-only models

gives the same likelihood but different parameter estimates.

theta an optional vector of starting values.

fixed an optional named numeric vector of predefined parameter values or a logical

(for coef) indicating to also return fixed parameters (only when type = "all").

scale a logical indicating if (internal) scaling shall be applied to the model coefficients.

optim a list of optimisers as returned by mltoptim

args a list of arguments for lpmvnorm.

fit character vector describing how to fit the model. The default is joint likelihood

estimation of all parameters, pseudo fixes the marginal parameters, sequential starts with a univariate model and sequentially adds models, keeping the parameters of previously added models fit. ACS implements Alternate Convex Search, starting with pseudo and, in a second step, fixing the marginal parameters. This

is iterated for ACSiter iterations.

ACSiter number of iterations for fit = "ACS".

Mmlt 15

#### **Details**

The function implements multivariate conditional transformation models as described by Klein et al (2020). Below is a simple example for an unconditional bivariate distribution. See demo("undernutrition", package = "tram") for a conditional three-variate example.

#### Value

An object of class Mmlt with coef and predict methods.

mtram

Transformation Models for Clustered Data

## Description

Marginally interpretable transformation models for clustered data.

mtram 17

#### Usage

#### **Arguments**

object A tram object.

formula A formula specifying the random effects.

data A data frame.

grd A sparse grid used for numerical integration to get the likelihood.

Hessian A logical, if TRUE, the hessian is computed and returned.

tol numerical tolerance.

#### **Details**

. . .

A Gaussian copula with a correlation structure obtained from a random intercept or random intercept / random slope model (that is, clustered or longitudinal data can by modelled only) is used to capture the correlations whereas the marginal distributions are described by a transformation model. The methodology is described in Barbanti and Hothorn (2022) and examples are given in the mtram package vignette.

Only coef() and logLik() methods are available at the moment, see vignette("mtram", package = "tram") for worked examples.

#### Value

An object of class tram with coef() and logLik() methods.

Additional argument.

#### References

Luisa Barbanti and Torsten Hothorn (2023). A Transformation Perspective on Marginal and Conditional Models, *Biostatistics*, doi:10.1093/biostatistics/kxac048.

```
### For illustrations see
## vignette("mtram", package = "tram")
## or
## demo("mtram", package = "tram")
```

18 perm\_test

perm\_test

Permutation Transformation Tests

#### **Description**

P-values for a parameter in a linear transformation model and corresponding confidence intervals obtained from by the permutation principle

#### Usage

```
perm_test(object, ...)
## S3 method for class 'tram'
perm_test(object, parm = names(coef(object)),
    statistic = c("Score", "Likelihood", "Wald"),
    alternative = c("two.sided", "less", "greater"),
    nullvalue = 0, confint = TRUE, level = .95,
    Taylor = FALSE, block_permutation = TRUE, maxsteps = 25, ...)
```

#### **Arguments**

object an object of class tram

parm a vector of names of parameters to be tested. These parameters must be present

in object.

statistic a character string specifying the statistic to be permuted. The default Score is

the classical permutation test for the esiduals of a model excluding the parameter parm. Only available for nullvalue =  $\emptyset$ , confidence intervals are not available. Permuting the likelihood or the model coefficients under the nullvalue is highly

expermimental as are the corresponding confidence intervals.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided"

(default), "greater" or "less".

nullvalue a number specifying an optional parameter used to form the null hypothesis.

confint a logical indicating whether a confidence interval should be computed. Score

confidence intervals are computed by default. A 1st order Taylor approximation to the Score statistic is used with Taylor = TRUE (in case numerical inversion of the score statistic fails, Wald-type confidence intervals relying from this approximation are returned). For the remaining likelihood and Wald statistics, confidence intervals are highly experimental (and probably not worth looking

at).

level the confidence level.

block\_permutation

a logical indicating wheather stratifying variables shall be interpreted as blocks

defining admissible permutations.

Taylor a logical requesting the use of a 1st order Taylor approximation when inverting

the score statistic.

perm\_test 19

```
number of function evaluations when inverting the score statistic for computing confidence intervals.

... additional arguments to independence_test.
```

#### **Details**

Permutation test for one single parameters in the linear predictor of object is computed. This parameters must be present in object. This is somewhat experimental and not recommended for serious practical use (yet!).

#### Value

An object of class htest or a list thereof. See Coxph for an example.

```
## Tritiated Water Diffusion Across Human Chorioamnion
## Hollander and Wolfe (1999, p. 110, Tab. 4.1)
diffusion <- data.frame(</pre>
    pd = c(0.80, 0.83, 1.89, 1.04, 1.45, 1.38, 1.91, 1.64, 0.73, 1.46,
           1.15, 0.88, 0.90, 0.74, 1.21),
    age = factor(rep(c("At term", "12-26 Weeks"), c(10, 5)))
)
### plot the two quantile functions
boxplot(pd ~ age, data = diffusion)
### the Wilcoxon rank sum test, with a confidence interval
### for a median shift
wilcox.test(pd ~ age, data = diffusion, conf.int = TRUE, exact = TRUE)
### a corresponding parametric transformation model with a log-odds ratio
### difference parameter, ie a difference on the log-odds scale
md <- Colr(pd ~ age, data = diffusion)</pre>
### assess model fit by plotting estimated distribution fcts
agef <- sort(unique(diffusion$age))</pre>
col <- c("black", "darkred")</pre>
plot(as.mlt(md), newdata = data.frame(age = agef),
     type = "distribution", col = col)
legend("bottomright", col = col, lty = 1, legend = levels(agef),
       bty = "n", pch = 19)
## compare with ECDFs: not too bad (but not good, either)
npfit <- with(diffusion, tapply(pd, age, ecdf))</pre>
lines(npfit[[1]], col = col[1])
lines(npfit[[2]], col = col[2])
### Wald confidence interval
confint(md)
### Likelihood confidence interval
confint(profile(md))
```

20 Polr

Polr

Ordered Categorical Regression

## **Description**

Some regression models for ordered categorical responses

## Usage

```
Polr(formula, data, subset, weights, offset, cluster, na.action = na.omit,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"), ...)
```

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.

score\_test 21

na.action a function which indicates what should happen when the data contain NAs. The

default is set by the na.action setting of options, and is na.fail if that is

unset.

method a character describing the link function.

... additional arguments to tram.

#### **Details**

Models for ordered categorical responses reusing the interface of polr. Allows for stratification, censoring and trunction.

The model is defined with a negative shift term, thus exp(coef()) is the multiplicative change of the odds ratio (conditional odds for reference divided by conditional odds of treatment or for a one unit increase in a numeric variable). Large values of the linear predictor correspond to large values of the conditional expectation response (but this relationship is nonlinear).

#### Value

An object of class Polr, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

#### References

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

## **Examples**

```
data("wine", package = "ordinal")
library("MASS")
polr(rating ~ temp + contact, data = wine)
Polr(rating ~ temp + contact, data = wine)
```

score\_test

Transformation Score Tests and Confidence Intervals

#### **Description**

P-values and confidence intervals for parameters in linear transformation models obtained from by the score test principle 22 Survreg

#### Usage

```
score_test(object, ...)
## S3 method for class 'tram'
score_test(object, parm = names(coef(object)),
    alternative = c("two.sided", "less", "greater"), nullvalue = 0,
    confint = TRUE, level = .95, Taylor = FALSE, maxsteps = 25, ...)
```

## **Arguments**

object an object of class tram

parm a vector of names of parameters to be tested. These parameters must be present

in object.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided"

(default), "greater" or "less".

nullvalue a number specifying an optional parameter used to form the null hypothesis.

confint a logical indicating whether a confidence interval should be computed. Score

confidence intervals are computed by default. A 1st order Taylor approximation to the Score statistic is used with Taylor = TRUE (in case numerical inversion of the score statistic fails, Wald confidence intervals relying from this approxima-

tion are returned).

level the confidence level.

Taylor a logical requesting the use of a 1st order Taylor approximation when inverting

the score statistic.

maxsteps number of function evaluations when inverting the score statistic for computing

confidence intervals.

... additional arguments, currently ignored.

#### **Details**

Score tests and confidence intervals for the parameters in the linear predictor of object are computed. These parameters must be present in object.

## Value

An object of class htest or a list thereof. See Coxph for an example. A corresponding permutation test for parameters in a transformation models is available in perm\_test.

Survreg	Parametric Survival Models	

## Description

Weibull, log-normal, log-logistic and other parametric models (not exclusively) for survival analysis

Survreg 23

#### Usage

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under tram and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised.
offset	this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases.
cluster	optional factor with a cluster ID employed for computing clustered covariances.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset.
dist	character defining the conditional distribution of the (not necessarily positive) response, current choices include Weibull, logistic, normal, exponential, Rayleigh, log-normal (same as log-gaussian), or log-logistic.
scale	a fixed value for the scale parameter(s).
	additional arguments to tram.

#### **Details**

Parametric survival models reusing the interface of survreg. The parameterisation is, however, a little different, see the package vignette.

The model is defined with a negative shift term. Large values of the linear predictor correspond to large values of the conditional expectation response (but this relationship is nonlinear). Parameters are log-hazard ratios comparing a reference with treatment (or a one unit increase in a numeric variable).

#### Value

An object of class Survreg, with corresponding coef, vcov, logLik, estfun, summary, print, plot and predict methods.

24 tram

#### References

Torsten Hothorn, Lisa Moest, Peter Buehlmann (2018), Most Likely Transformations, *Scandinavian Journal of Statistics*, **45**(1), 110–134, doi:10.1111/sjos.12291.

#### **Examples**

```
data("GBSG2", package = "TH.data")
library("survival")
survreg(Surv(time, cens) ~ horTh, data = GBSG2)
Survreg(Surv(time, cens) ~ horTh, data = GBSG2)
```

tram

Stratified Linear Transformation Models

## Description

Likelihood-inference for stratified linear transformation models, including linear shift-scale transformation models.

#### Usage

#### **Arguments**

formula	an object of class "formula": a symbolic description of the model structure to be fitted. The details of model specification are given under Details and in the package vignette.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used in the fitting process.

tram 25

weights an optional vector of case weights to be used in the fitting process. Should be NULL or a numeric vector. If present, the weighted log-likelihood is maximised. offset this can be used to specify an \_a priori\_ known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. cluster optional factor with a cluster ID employed for computing clustered covariances. na.action a function which indicates what should happen when the data contain NAs. The default is set to na.omit. distribution character specifying how the transformation function is mapped into probabilities. Available choices include the cumulative distribution functions of the standard normal, the standard logistic and the standard minimum extreme value distribution. frailty character specifying the addition of a frailty term, that is, a random component added to the linear predictor of the model, with specific distribution (Gamma, inverse Gaussian, positive stable). transformation character specifying the complexity of the response-transformation. For discrete responses, one parameter is assigned to each level (except the last one), for continuous responses linear, log-linear and smooth (parameterised as a Bernstein polynomial) function are implemented. logical specifying if a likelihood-ratio test for the null of all coefficients in the LRtest linear predictor being zero shall be performed. prob two probabilities giving quantiles of the response defining the support of a smooth Bernstein polynomial (if transformation = "smooth"). a vector of two elements; the support of a smooth Bernstein polynomial (if support transformation = "smooth").

bounds an interval defining the bounds of a real sample space.

add add these values to the support before generating a grid via mkgrid.

order integer >= 1 defining the order of the Bernstein polynomial (if transformation

= "smooth").

logical defining the sign of the linear predictor. negative

remove\_intercept

scale

logical defining if the intercept shall be removed from the linear shift predictor in favour of an (typically implicit) intercept in the baseline transformation. If FALSE, the linear shift predictor has an intercept (unless -1 is added to the formula) but the baseline transformation is centered. For linear transformation models, this does not change the in-sample log-likelihood. For shift-scale transformation models, using FALSE ensures that centering of variables in the linear shift predictor does not affect the corresponding estimates and standard errors. Note that linear scale predictors are always fitted without intercept.

logical defining if variables in the linear predictor shall be scaled. Scaling is

internally used for model estimation, rescaled coefficients are reported in model

output.

scale\_shift a logical choosing between two different model types in the presence of a scaling

term, see ctm.

26 tram

extrapolate logical defining the behaviour of the Bernstein transformation function outside

support. The default FALSE is to extrapolate linearily without requiring the second derivative of the transformation function to be zero at support. If TRUE,

this additional constraint is respected.

sparse\_nlevels integer; use a sparse model matrix if the number of levels of an ordered factor is

at least as large as sparse\_nlevels.

log\_first logical; if TRUE, a Bernstein polynomial is defined on the log-scale.

model\_only logical, if TRUE the unfitted model is returned.

constraints additional constraints on regression coefficients in the linear predictor of the

form lhs %\*% coef(object) >= rhs, where lhs and rhs can be specified as a character (as in glht) or by a matrix lhs (assuming rhs = 0), or as a list

containing the two elements 1hs and rhs.

... additional arguments.

#### **Details**

The model formula is of the form  $y \mid s \sim x \mid z$  where y is an at least ordered response variable, s are the variables defining strata and x defines the linear predictor. Optionally, z defines a scaling term (see ctm).  $y \sim x$  defines a model without strata (but response-varying intercept function) and y  $\mid s \sim 0$  sets-up response-varying coefficients for all variables in s.

The two functions tram and tram\_data are not intended to be called directly by users. Instead, functions Coxph (Cox proportional hazards models), Survreg (parametric survival models), Polr (models for ordered categorical responses), Lm (normal linear models), BoxCox (non-normal linear models) or Colr (continuous outcome logistic regression) allow direct access to the corresponding models.

The model class and the specific models implemented in **tram** are explained in the package vignette of package **tram**. The underlying theory of most likely transformations is presented in Hothorn et al. (2018), computational and modelling aspects in more complex situations are discussed by Hothorn (2018).

#### Value

An object of class tram inheriting from mlt.

#### References

```

#### Arguments

object, formula, x

a fitted stratified linear transformation model inheriting from class tram. PI also

takes a numeric vector in the default method.

data an optional data frame.

with\_baseline logical, if TRUE all model parameters are returned, otherwise parameters describ-

ing the baseline transformation are ignored.

as.lm logical, return parameters in the lm parameterisation if TRUE.

as.survreg logical, return parameters in the survreg parameterisation in TRUE.

parm model parameters, including baseline parameters.

complete currently ignored

newdata an optional data frame of new observations.

reference an optional data frame of reference observations, or a numeric vector of refer-

ence values.

type type of prediction, current options include linear predictors ("lp", of x vari-

ables in the formula  $y \mid s \sim x$ ), transformation functions ("trafo") or distribution functions on the scale of the cdf ("distribution"), survivor function, density function, log-density function, hazard function, log-hazard function, cu-

mulative hazard function or quantile function.

which type of plot, either a QQ plot of the probability-integral transformed observa-

tions ("QQ-PIT"), of the baseline transformation of the whole distribution.

what type of model matrix / linear predictor: shifting returns model model matrix /

linear predictor for shift term, scaling for the scale term.

confidence type of uncertainty assessment.

level confidence level.

K number of grid points in the response, see plot.ctm.

cheat reduced number of grid points for the computation of confidence bands, see

confband.

col line color.
fill fill color.
lwd line width.
lty line type.

prob	a numeric vector of probabilities
link	a character identifying a link function.
one2one	logical, compute the ROC curve (and derived measures) comparing each row in newdata with each row in reference (FALSE, the default), or compare observations rowwise (TRUE).
	additional arguments to the underlying methods for class mlt, see mlt-methods.

#### **Details**

coef can be used to get (and set) model parameters, logLik evaluates the log-likelihood (also for parameters other than the maximum likelihood estimate); vcov returns the estimated variance-covariance matrix (possibly taking cluster into account) and and estfun gives the score contribution by each observation. predict and plot can be used to inspect the model on different scales.

PI computes the probabilistic index (or concordance probability or AUC) for all observations in newdata, relative to reference, ie the probability

$$P(Y_1 \leq Y_0 \mid x_0, x_1)$$

of observing a smaller value of a randomly sampled observation conditional on  $x_1$  compared to a randomly sampled reference observation, which is conditional on  $x_0$ . This is equivalent to the area under the receiver operating curve (ROC). The probability only applies within strata, response-varying coefficients are not allowed.

Under the same setup, OVL gives the overlap coefficient, which is one minus the total variation and one minus half the  $L_1$  distance between the two conditional densities. The overlap coefficient is identical to the Youden index and the Smirnov statistic.

PI and friends also accept an argument conf.level which triggers computation of simultaneous Wald confidence intervals for these measures. Arguments in ... are forwarded to glht.
